## Description

Health care is the prevention, diagnosis, treatment, amelioration, or cure of disease, illness, injury, and other physical and mental problems in people. Specialists in the medical and allied health fields provide health treatment. Doctors, dentists, pharmacists, midwives, nurses, optometrists, audiologists, psychologists, occupational therapists, physical therapists, athletic trainers, and others are among the health professions. Work in primary care, secondary care, and tertiary care, as well as public health, are all included.

Health care involves more than just the delivery of services to patients; it encompasses a wide range of linked industries and is embedded in a larger framework of finance and governance. A health system, also known as a health care system or a healthcare system, is a collection of people, institutions, and resources that work together to provide health care to individuals in need.

### Healthcare industry

Several sectors make up the healthcare industry, all of which are dedicated to providing health-related services and products. The International Standard Industrial Classification of the United Nations categorises health care as consisting of hospital activities, medical and dental practice activities, and "other human health activities" as a basic framework for describing the sector. The final category includes activities performed by or under the direction of nurses, midwives, physiotherapists, scientific or diagnostic laboratories, pathology clinics, residential health facilities, patient advocates, or other allied health professionals. The International Standard Industrial Categorization of All Economic Activities (ISIC) is a classification system used by the United Nations to categorise industries. ISIC has been widely used in the sectors of employment and health data to classify data according to the type of economic activity. The United Nations Statistics Division is in charge of keeping track of it.

## Health care research

Many health-care interventions have improved in quantity and quality as a result of scientific advances, such as the medical model of health, which focuses on the eradication of illness through diagnosis and successful treatment. Health research, biological research, and pharmaceutical research have all achieved significant gains, laying the groundwork for evidence-based medicine and evidence-based practice in health care delivery. Patients are commonly involved in health-care research, therefore questions about who to engage and how to engage them become vital to consider when attempting to actively incorporating them in studies. While there is no one best practise, the findings of a systematic review on patient engagement show that patient selection procedures should take into account both patient availability and willingness to interact.

### Health care financing

There are five basic ways to fund health-care systems in general:

Taxation levied on the state, county, or municipality as a whole.

Health insurance provided by the government.

Health insurance is available on a voluntary or private basis.

Payments made out of pocket.

Donations to health-related organisations.

A health system, also known as a medical system or a healthcare system, is a group of people, institutions, and resources that work together to deliver health care services to meet the needs of certain populations. There are as many health systems as there are countries on the planet, each with its own history and organisational structure. Despite the fact that nations must build and grow health systems based on their needs and resources, primary health-care and public health programmes are common aspects in practically all health systems.
